The following is the performance of the old model and new model on Split 1 and Split 2.

	Old Code	New Code
Split 1	77.60%	73.22%
Split 2	32.01%	32.01%

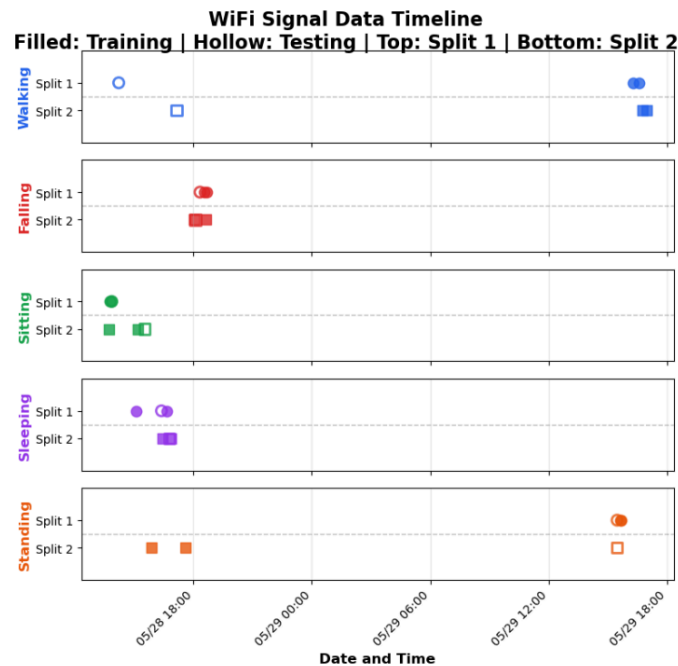

* percentage represents the validation accuracy

The improvement in model performance seems driven more by the data split than the code changes. To better estimate performance, I will repeatedly generate random splits: 20 training sessions (4 per activity) and 5 validation sessions (1 per activity). I will compare two strategies — randomly scattered sessions vs. adjacent sessions — to assess the impact of temporal proximity between training and validation data.

	Scattered Sessions	Adjacent Sessions
Sample 1	0.3657	0.7569
Sample 2	0.3087	0.6656
Sample 3	0.4966	0.8447
Sample 4	0.3597	0.9053
Sample 5	0.3146	0.8243
Average	0.3691	0.7994

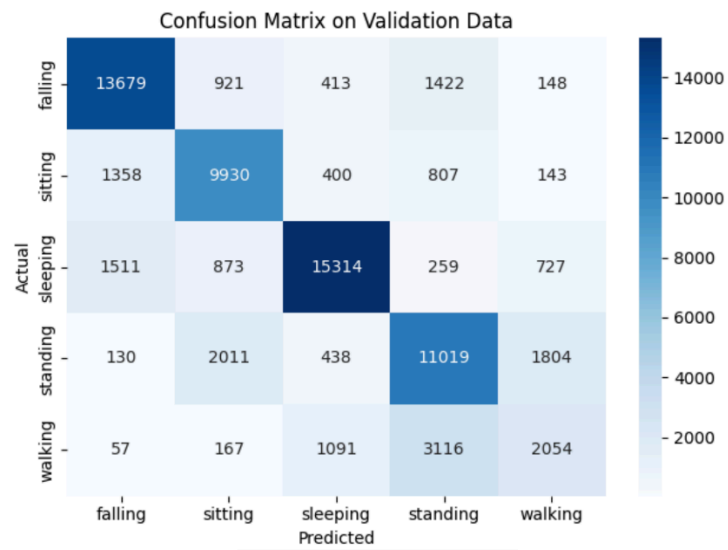

When the training and validation data are close in time, the model achieves high accuracy. However, when they are far apart, accuracy drops significantly. This indicates that even if the model is trained on the entire dataset, it may still perform poorly in real-time testing. Therefore, to more accurately assess real-time performance, the evaluation should use training and testing data that are far apart in time.

This hypothesis may explain why the model performs poorly on split 2 but better on split 1.

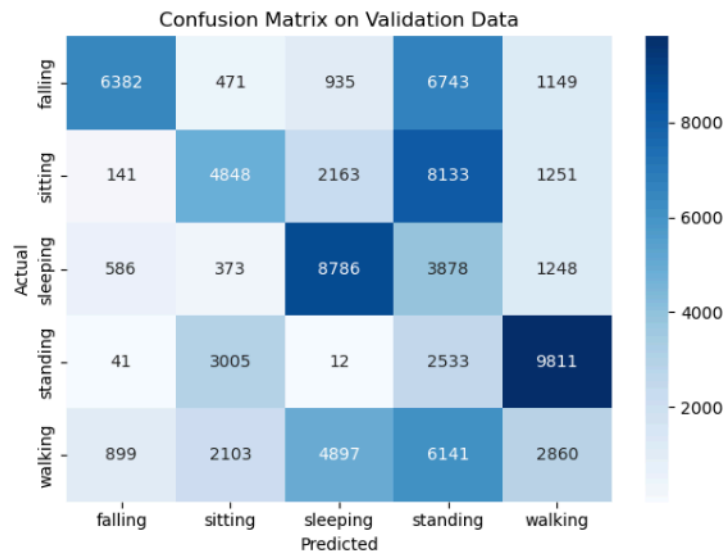

From the plot, we can anticipate that the model trained with split 1 will perform well on all activities except walking, where the test data (hollow dot) is far away from training data (filled dot). For split 2, the model is likely to perform worse on walking and standing. These predictions align with the patterns observed in the confusion matrices.
